Summary

The complex 16p11.2 Deletion Syndrome (16pdel) is accompanied by neurological disorders, including epilepsy, autism spectrum disorder and intellectual disability. We demonstrated that 16pdel iPSC differentiated neurons from affected people show augmented local field potential activity and altered ceramide-related lipid species relative to unaffected. *FAM57B*, a poorly characterized gene in the 16p11.2 interval, has emerged as a candidate tied to symptomatology. We found that FAM57B modulates ceramide synthase (CerS) activity, but is not a CerS per se. In *FAM57B* mutant human neuronal cells and zebrafish brain, composition and levels of sphingolipids and glycerolipids associated with cellular membranes are disrupted. Consistently, we observed aberrant plasma membrane architecture and synaptic protein mislocalization, which were accompanied by depressed brain and behavioral activity. Together, these results suggest that haploinsufficiency of *FAM57B* contributes to changes in neuronal activity and function in 16pdel Syndrome, through a crucial role for the gene in lipid metabolism.

Introduction

16p11.2 Deletion (16pdel) Syndrome, a severe and prevalent neurodevelopmental disorder, is a copy number variant with deletion of ~600 kb from chromosome 16, encompassing 25 core protein-coding genes. This haploinsufficiency syndrome is estimated to affect ~1 in 2500 worldwide and is tightly associated with autism spectrum disorder (ASD), language and intellectual disability, seizures, attention-deficit/hyperactivity disorder, macrocephaly, hypotonia and obesity (D'Angelo et al., 2016, Hanson et al., 2015, Zufferey et al., 2012, Egolf et al., 2019, Maillard et al., 2015). Strong indications of synaptic defects are associated with 16pdel symptoms, particularly epilepsy (Fetit et al., 2020, Kleinendorst et al., 2020) and ASD (Fetit et al., 2020, Kim et al., 2020, Maillard et al., 2015, Ouellette et al., 2020, Sebat et al., 2007, Pinto et al., 2010, Zufferey et al., 2012), as well as links to metabolic defects (Hoytema van Konijnenburg et al., 2020).

37   Previously, analysis in the zebrafish model suggested that *FAM57B* is a pivotal hub gene in the

38   16p11.2 interval, that encodes a protein proposed to be a ceramide synthase (Yamashita-Sugahara et al.,

39   2013). Using a pairwise partial loss of function screen for zebrafish embryonic brain morphology, we found that

40   *fam57b* interacted with numerous other 16p11.2 interval genes, suggesting haploinsufficiency of *FAM57B* is

41   critical in 16pdel Syndrome etiology (McCammon et al., 2017). FAM57B (family with sequence similarity 57,

42   member B) is a Tram-Lag-CLN8 (TLC) family member, containing a domain of roughly 200 amino acids found

43   in several other proteins, including ceramide synthases (CerS, the Lag of TLC) (Pewzner-Jung et al., 2006).

44   Ceramides are sphingolipids (SLs) which are key membrane components and also act as signaling molecules

45   to modulate proliferation, apoptosis, inflammation, cell cycle arrest and ER stress (Grosch et al., 2012). In

46   humans, mutations in some of the 6 known CerS are associated with autism, epilepsy and intellectual disability

47   (Vanni et al., 2014, Egawa et al., 2015, Ranta et al., 1999). In this study, to further assess the predicted

48   connection with 16pdel Syndrome, we examined FAM57B function through a multidisciplinary approach,

49   across human cells and the zebrafish system.

50

51   **Results**

52   **Augmented network activity in 16pdel neuron cultures**

53   Based on previous data, we hypothesized that 16pdel neurons would show an altered lipid profile due

54   to contributions of *FAM57B* and possibly other 16pdel genes with predicted roles in metabolism (McCammon

55   et al., 2017). To test this, we prepared neurons from 16pdel carrier induced-pluripotent stem cells (iPSC), part

56   of the Simons VIP Consortium, and unaffected control iPSC in culture (Simons Vip, 2012) (**Supp Table 1**).

57   Neural progenitor cells were differentiated into cortical neurons, since the cortex has consistently shown

58   anatomical differences in 16pdel affected individuals (Martin-Brevet et al., 2018, Maillard et al., 2015, Hinkley

59   et al., 2019, Lin et al., 2015, Qureshi et al., 2014, Blackmon et al., 2018). After one month in culture,

60   immunocytochemistry (ICC) indicated mature neurons by presence of vesicular glutamate 1 and 2 receptors

61   (VGlut1/2) (**Supp Figs. 1a,b**), the synaptic markers PSD95 (**Supp Fig. 1b**) and Synaptotagmin-1 (Syt1).

62   Cultures of control and 16pdel (proband) differentiated neurons showed similar percentages of mature neurons

63   by these criteria. Quantitative analysis was performed to determine equivalent maturation between control and

64   16pdel differentiated neurons. Production of synaptic proteins was measured by colocalization analysis,

65   indicating neuronal somas that were Synaptotagmin-1 positive additionally colocalized with PSD-95 (**Supp

66   Table 2**).

67   To further characterize these neurons, we probed network electrical activity by multi-electrode array

68   (MEA). Spontaneous activity of differentiated neurons was measured over thirty minutes; first in culture media,

69   followed by physiological solution and last in high potassium chloride solution. Comparing grouped genotypes,

70   we recorded an increased frequency of Local Field Potentials (LFPs) in 16pdel proband neuron cultures

71   relative to controls, indicating 16pdel neurons display heightened spontaneous and evoked activity compared

72   to unaffected control (**Fig. 1a**). Examining individual patient cell lines, we observed relatively similar MEA

2

73 activity in controls (black), and increased electrical activity in 16pdel neuron cultures (grey) (**Supp Fig. 2a**).

74 Interestingly, female 16pdel neuron cultures showed statistically increased LFP frequency compared to male

75 16pdel neuron cultures when measured in media and High KCl solution (**Fig. 1b**). Sex differences were also

76 observed in LFP firing and bursting properties, with increased burst frequency of female 16pdel neurons

77 compared to male in media (**Fig. 1c**). While behavioral deficits have been widely observed among male mouse

78 16pdel models, a recent report found stress-related sex differences in a female 16p11.2 deletion mouse model.

79 Thus, Giovanniello *et al.* discovered an increase in activity in central amygdala neurons projecting to the

80 globus pallidus in female, but not male, 16pdel model mice (Giovanniello, 2021). Our data consistently suggest

81 sex-specific differences between activity of 16pdel and control neurons. These findings expand previous

82 observations that demonstrated larger cell size and deficits in synaptic density in 16pdel neurons compared to

83 control (Deshpande et al., 2017).

84

85 **Significant lipid class and individual species changes indicates complexity of 16pdel Syndrome.**

86 Using differentiated 16pdel and control neurons, we compared their lipid cohorts using untargeted

87 lipidomics (**Table S1 - iPSC Neuron Lipidomics**). Consistent with predictions, many significant changes were

88 observed in total lipid classes between 16pdel and control neurons (**Fig. 2a**). Levels of SLs (ceramide (Cer)

89 and sphingomyelin (SM)) and glycerolipids (GL) (lysophosphatidylethanolamine (LPE),

90 phosphatidylethanolamine (PE), monoacylglycerol (MG)) were significantly decreased, while GL (triacylglycerol

91 (TG)) levels significantly increased. Analyzing lipid composition, we found similar levels of unsaturated and

92 saturated species between 16pdel and control neurons, but differences in saturation of acyl carnitine (AcCa)

93 (unsaturated control 33.78% vs 16pdel 55.16%, and saturated control 66.22% and 16pdel 44.84%) and TG

94 (unsaturated control 71.15% vs 16pdel 80.28%, and saturated control 28.85% and 16pdel 19.72%) (**Fig. 2b**).

95 Polyunsaturated fatty acids (PUFAs) are important in the brain, where they are essential for signaling and

96 membrane structure (Bazinet and Laye, 2014). Chain length analysis indicated large differences in

97 lysophosphatidylglycerol (LPG) (long chain control 85.76% vs 16pdel 75.55%) and phosphatidylglycerol (PG)

98 (long chain control 71.78% vs 16pdel 51.88%). While having a similar ratio of long and very long chain PE

99 species (**Fig. 2b**), analysis of individual lipid species demonstrated significantly decreased levels of several

100 PE(18:22) species in 16pdel neurons relative to control (**Fig. 2c**). Additionally, decreased Cer(18) species were

101 observed in 16pdel (**Fig. 2d**). Comparing MG and TG, MG(18:0) decreased while many TG(18:1,18:2,18:3)

102 increased (**Fig. 2e,f**). Together, this analysis identifies differences in metabolism of ceramides and GLs in

103 16pdel neurons that are critical for function of the ER, mitochondria and plasma membrane (Flis and Daum,

104 2013). The shift in saturation and tail length of GLs between 16pdel and control neurons suggests a

105 dysfunctional neuronal membrane.

106

107 **FAM57B functions as a ceramide synthase modulator**

3

108   We considered that the extensive lipid differences between 16pdel and control neurons may partly
109   result from FAM57B activity. The function of this protein is not clear, although a single report suggests that
110   FAM57B has ceramide synthase activity (Yamashita-Sugahara et al., 2013). However, sequence analysis
111   indicates that while FAM57B is part of the TLC protein family, including ceramide synthases (CerS), FAM57B
112   has little sequence similarity to CerS, even in the TLC domain (**Supp Fig. 3**). To assess whether FAM57B is a
113   *bone fide* CerS, it was expressed in *CerS2$^{-/-}$ (KO)* HEK293T cells, which lack endogenous CerS2 activity
114   (Tidhar et al., 2012) (**Fig. 3a**). No CerS2 activity was detected in *CerS2 KO* cells upon transfection of FAM57B
115   alone. However, co-transfection of FAM57B with CerS2 resulted in a significant increase in CerS2 activity
116   compared to transfection of CerS2 alone (**Fig. 3a**), suggesting that FAM57B might modulate CerS2 activity.
117   There are six CerS isoforms in mammals, where each uses a restricted subset of acyl CoAs of defined chain
118   length for ceramide synthesis(Levy and Futerman, 2010). To assess whether FAM57B can modulate other
119   members of the mammalian CerS family; we expressed CerS5 and CerS6 with or without co-transfection of
120   FAM57B in wildtype HEK293T cells. Upon co-transfection of CerS2 with FAM57B in wildtype HEK293T cells,
121   levels of CerS2 activity and expression were significantly increased compared to CerS2 alone (**Fig. 3b**). While
122   co-transfection of FAM57B with CerS5 did not alter expression nor activity of this CerS (**Fig. 3c**), an opposite
123   trend was seen upon co-transfection of FAM57B with CerS6, whose activity decreased upon co-transfection
124   with FAM57B (**Fig. 3c**). These results suggest that FAM57B affect protein levels and activity of certain CerS
125   isoforms, and may do so by an indirect mechanism, dependent on interaction of the two proteins. This
126   hypothesis was confirmed by immunoprecipitation, in which Flag-tagged FAM57B was able to interact with all
127   three HA-tagged CerS isoforms (**Fig. 3d**). These data newly implicate FAM57B as a modulator of CerS, but
128   refute a previous report that this protein functions as a CerS (Yamashita-Sugahara et al., 2013).
129

130   ***FAM57B* modulates lipid cohorts and synaptic proteins in human cells**
131   The intriguing functional differences between 16pdel and control neurons raises the question of
132   whether *FAM57B* haploinsufficiency contributes to these differences. To address this, we used the human
133   neuroblastoma line SH-SY5Y to create knockout (*FAM57B KO*) and *FAM57B* heterozygote (*FAM57B HET*)
134   lines, using CRISPR-Cas9 editing. SH-SY5Y cells have proven useful for studying neuronal properties and
135   function (Kovalevich J, 2013). After confirmation of CRISPR induced genome editing by next generation
136   sequencing, FAM57B protein depletion was confirmed by western analysis (**Supp Fig. 4**). For our studies, SH-
137   SY5Y cells were differentiated into neurons after incubation in media containing retinoic acid. Overall, total lipid
138   classes showed significant differences between *FAM57B KO* and WT (wildtype), specifically, increased ChE
139   and MG (**Fig. 4a**, **Table S2 - SH-SY5Y Lipidomics)**. Comparing *FAM57B HET* to WT, we observed increased
140   LPC (**Fig. 4b**). Additionally, relative to *FAM57B HET*, we found HexCer and PG significantly decreased while
141   ChE increased in *FAM57B KO* cells (**Fig. 4c**).
142   Notably, lipid class differences observed between *FAM57B KO*, *FAM57B HET* and WT were similarly
143   altered in 16pdel patient neurons compared to controls (**Fig. 2a**). This, in both *FAM57B KO* and *FAM57B HET*

144 relative to WT, we observed increased abundance of PE(18:0,18:1,22:4,22:5) (**Fig. 4d**), Cer(d18:1) (**Fig. 4e**),

145 MG(18:0) (**Fig. 4f**), and with decreased abundance of TG(16:0,16:1,18:0,18:1,18:2,22:6) (**Fig. 4g**). These

146 differences are similar to those seen in 16pdel relative to control neurons (**Fig. 2c-f**). In *FAM57B KO* relative to

147 WT, there was increased abundance of MG and decreased abundance TG (**Fig. 4f,g**), as for 16pdel neurons

148 compared to control (**Fig. 2a,e,f**). The alterations in lipid cohorts between *FAM57B KO* and *FAM57B HET*

149 human neurons is similar to lipid changes in 16pdel neurons compared to control, and consistent with a role for

150 FAM57B in dosage-sensitive lipid regulation. The similarities in lipid cohort alterations between *FAM57B KO*

151 compared to *FAM57B HET* in SH-SY5Y human neurons and 16pdel neurons, is consistent with a role for

152 FAM57B in dosage-sensitive, lipid regulation, including tight regulation of HexCer (**Fig. 4c**).

153 To understand the consequence of *FAM57B loss of function* on neuronal maturation and function, we

154 probed synaptic composition. Synaptosomes, comprising the pre- and postsynaptic membranes and

155 postsynaptic density, were isolated from unfixed cells and processed by MS/MS (**Table S3 - SH-SY5Y**

156 **Synaptosome MSMS)**. Synaptosomes from *FAM57B KO* cells showed significantly decreased abundance of

157 over 100 proteins relative to WT (**Fig. 5a**). In contrast, *FAM57B HET* showed no statistically significant

158 changes in synaptosome protein composition relative to WT (**Fig. 5b**), with the exception of Dopamine Beta-

159 Hydroxylase (DBH). Among the top 20 significantly decreased proteins in the *FAM57B KO* synaptosomes were

160 those associated with protein trafficking, localization and stabilization (**Fig. 5c,d**). Additionally, we observed an

161 overall decrease in levels of hallmark synaptic proteins in *FAM57B KO* compared to *FAM57B HET* or *WT* (**Fig.**

162 **5e**). These decreases included α-internexin INA, small GTPase vesicle recycling RAB11B, SNARE protein

163 syntaxin STXBP1 and scaffolding protein YWHAZ. INA is a neurofilament subunit protein important for

164 neuronal cytoskeletal assembly and synaptogenesis localized to the post-synaptic terminal (Yuan and Nixon,

165 2016).

166 Separately, synaptosomes were isolated from differentiated SH-SY5Y cells and processed for lipidomic

167 analysis (**Table S4 - SH-SY5Y Synaptosome Lipidomics)**. Comparing lipids localized to the pre- and post-

168 synaptic terminals between *FAM57B KO* to WT neurons, significant changes in lipid abundances were

169 observed, notably in hexosylceramide (HexCer) and monoacylglycerol (MG) (**Fig. 5f**). Relative to WT, Hex2Cer

170 and MG abundances increased, while Hex1Cer and phosphatidic acid (PA) abundances decreased. No

171 statistically significant changes in lipid group abundances were observed between *FAM57B HET* relative to WT

172 or *FAM57B KO*. These results suggest altered lipid composition, due to loss of *FAM57B* function at developing

173 synapses impacts localization and/or trafficking of synaptic proteins in *FAM57B* mutant neurons. Together, the

174 data indicate that in human neurons mutant or heterozygous for *FAM57B,* there are significant changes in lipid

175 composition and regional synaptic protein abundance. The data are consistent with the suggestion that a

176 deficit in FAM57B function partly contributes to 16pdel neuronal anomalies relative to control. The smaller

177 changes observed in *FAM57B HET* relative to *FAM57B KO* suggests that other 16pdel genes contribute to

178 phenotypes in the haploinsufficient syndrome.

179

FAM57B is essential for Sphingolipid (SL) and Glycerolipid (GL) homeostasis in the developing brain.

16pdel alters brain structure and function, including neuroanatomical abnormalities and increased risk of psychiatric and other brain disorders (Niarchou et al., 2019, Owen et al., 2018). To understand how *FAM57B* contributes to brain development, we analyzed zebrafish, *Danio rerio*, a powerful system for analysis of neural development and neurodevelopmental disorders (Kalueff et al., 2014, Stewart et al., 2014, Xi et al., 2011, McCammon and Sive, 2015). The zebrafish genome includes two copies of the *fam57b* gene, *fam57ba* and *fam57bb*. We used CRISPR to build double (null) mutants, *fam57ba$^{-/-}$;fam57bb$^{-/-}$* (*fam57b mut*), and heterozygotes *fam57b$^{+/-}$;fam57bb$^{+/-}$ (fam57b het)*, to assess dosage effects of FAM57B.

To determine whether *fam57b* regulates lipid metabolites, we performed untargeted lipid profiling on *fam57b mut* and *fam57b het* zebrafish brain tissue at 7 days post-fertilization (7 dpf), an optimal timepoint for molecular and behavioral studies of a developing yet complex brain (**Table S5 - Zebrafish Larvae Brain Lipidomics)** (Tomasello and Sive, 2020). Striking differences in SL and GL lipid abundances were present in *fam57b mut* and *fam57b het* compared to wildtype (AB) zebrafish brain (**Fig. 6a,b**). By lipid class, there was a significant increase in Cer, LPE, MG and SM along with phosphatidylinositol (PI) and cardiolipin (CL) and decreased PS in *fam57b mut* compared to AB (**Fig. 6a**). A similar trend to *fam57b mut*, with increased hexosylceramide (HexCer) and decreased PS lipid classes, were defined in *fam57b het* brains compared to AB control. An overlap in lipid differences were observed between *fam57b mut* brains and FAM57B KO human neurons, with increased abundance of MG class, and Cer(d18:1) and MG(18:0) species (**Figs. 6a, 4a, 6d,e, 4d,e**). Many PE species similarly increased, PE(18:0,18:1,20:4), comparing *fam57b mut* and *FAM57B KO* to controls. An important finding across all systems compared, including 16pdel syndrome patient neurons, heterozygous and mutant *FAM57B* cells and larvae brains, is a change in ether-linked PE (**Figs. 2c, 4d, 6c,g**). Ether GLs differ in phase-transition temperature from gel to liquid crystalline and from lamellar to hexagonal phases, and are proposed to regulate properties of neuronal membranes (Paltauf, 1994, Lohner, 1996). In addition to PE, ceramides were altered in *fam57b mut* and *fam57b het* brain tissue compared to AB (**Fig. 4d,h**). Lipidomics resolved predominantly Cer(d18:1) species in zebrafish brains, which agrees with previously published ceramide composition at 7 dpf (Zhang et al., 2019). These findings suggest a key role for Fam57b in SL and GL regulation during brain development.

These data demonstrate that *fam57b* is crucial for regulation of SL and GL classes in the larval zebrafish brain, and that there is a gene dosage-dependent effect. The data in zebrafish brain are quite similar to changes seen in human neurons after FAM57B knockout (**Fig. 4**). These changes affect comparable lipid groups to those altered in 16pdel neurons relative to control, although they are not the same. For example, LPE significantly decreased in the 16pdel neurons (**Fig. 2a**), while the class remained unchanged or significantly increased in the *fam57b* het and null SH-SY5Y cells (**Fig. 4a-c**) and zebrafish brain (**Fig. 6a,b**), suggesting additional genes regulate 16pdel lipid metabolites or that these result from other differences between the tissue being compared.

216 **Changes in plasma membrane and associated proteins in *fam57b mut* and *fam57b het* brains**

217   Ceramide, hexosylceramide and GL species are integral to membrane composition, are differentially

218 distributed across inner and outer leaflets of the plasma membrane and contribute to lipid rafts (Kraft, 2016).

219 Given the changes in these lipids observed in *fam57b mut* brains, we predicted that plasma membrane

220 structure would also be altered. To assess lipid raft organization, fluorophore-conjugated Cholera Toxin subunit

221 B (CT-B), which binds ganglioside GM1 found in lipid rafts (Fishman et al., 1978), was injected into the

222 hindbrain ventricle of *fam57b mut* and AB zebrafish embryos at 24 hours post fertilization (hpf), when ventricles

223 are accessible for injection (Worstell et al., 2016) (**Fig. 7a**). Embryos fixed after 1-hour incubation

224 demonstrated a significant increase in punctate GM1 labeling in neural progenitor cells of *fam57b mut* brains

225 compared to AB (**Fig. 7b**). To asses changes in glycerophospholipid species in plasma membranes, we

226 stained with duramycin, a label for membrane PE (Marconescu and Thorpe, 2008). Mutant progenitors showed

227 statistically increased punctate PE staining, indicating altered PE localization that could impact membrane

228 architecture (**Fig. 7c**). The duramycin puncta may indicate exosomes or extracellular vesicles containing PE

229 (Beer et al., 2018). At 24 hpf, we did not observe changes in cell proliferation or cell death between *fam57b*

230 *mut* and AB (**Supp. Fig 5**). The data suggest that there is alteration in the plasma membrane of *fam57b mut*

231 brains relative to AB.

232   The changes in membranes of neural progenitor cells suggested that membrane protein localization

233 may also be altered. We therefore examined localization of membrane by biotinylation analysis. Freshly

234 dissected larval brains from *fam57b mut* or AB at 7 dpf were incubated with membrane impermeable biotin.

235 Surface proteins were affinity-purified and quantified by MS/MS (**Fig. 7d**, **Table S6 - Zebrafish Larvae Brain**

236 **Biotinylation MSMS)**. MS/MS analysis indicated that membrane-associated protein cohorts were similar

237 between *fam57b mut* and AB brains (**Fig. 7e**), however, a small group of proteins showed altered abundance.

238 In *fam57b mut* brains, the protein whose levels most significantly decreased (2-fold) relative to AB was

239 Synaptotagmin-1a (Syt1) (**Fig. 7e**). Syt1a, homologous to human SYT1, is a vesicle membrane protein that

240 acts as a calcium sensor and regulates synaptic and endocrine vesicle exocytosis (Fernandez et al., 2001,

241 Sorensen et al., 2003, Xu et al., 2007, Gustavsson and Han, 2009, Schonn et al., 2008). Syt1 protein domains

242 interact with the lipid bilayer, including GL PS that are altered in *fam57b mut* and *fam57b het* (**Fig. 5a,b**).

243 Mammalian Syt1 can modify PS, and is able to alter curvature strain on the membrane (Lai et al., 2011).

244   To investigate the decreased membrane abundance of Syt1 in the biotinylation assay, we performed

245 immunostaining on 7 dpf larvae brains (**Fig. 7f**). Whole larval brains were cleared and tertiary structure was

246 protected using SHIELD protocols. Slice imaging of dorsal brain view showed that Syt1 protein was largely

247 confined to projections of neurons throughout the AB brain, both GABAergic (GAD65/67) and non-GABAergic,

248 while *fam57b mut* brains showed ectopic expression throughout the brain (**Fig. 7f**). By western blot, we found

249 no change in total brain Syt1 between *fam57b mut* and AB, suggesting that immunostaining demonstrates

250 Syt1a mislocalization (**Fig. 7g, Supp Fig. 6**). Imaging also revealed anatomical changes in the larval *fam57b*

251 *mut* brain, including tectum and corpus cerebelli (**Fig. 7f**).

252   Together, these results indicate that in the brain, relative to wildtype, *fam57b mut* animals show

253 changes in lipids, membrane structure and membrane protein association, including the synaptic regulator

254 Syt1 and others functioning at synapses. The data indicate that *fam57b* is required for membrane structure and

255 neuronal architecture.

256

257 **Pre- and post-synaptic proteins depleted after loss of *FAM57B***

258   To examine the implications of Syt1 mis-localization on synaptic composition, we isolated

259 synaptosomes from freshly dissected and unfixed brains of *fam57b mut* or AB larvae (**Table S7 - Zebrafish**

260 **Larvae Brain Synaptosome MSMS)**. Proteomic profiling indicated a group of proteins whose representation

261 significantly increased, and another larger group whose representation significantly decreased in *fam57b mut*

262 compared to AB (**Fig. 7h**). Interestingly, we observed a decrease of the Synaptotagmin family member Syt2a-

263 like protein, similar to human SYT2, with analogous function to SYT1. Gene ontology (GO-Slim and Panther

264 Protein Class ontology) defined synaptic protein groups found only in the decreased synaptosome protein

265 group (**Fig. 7i, 7j**). Annotations in the decreased group included synapse and synapse part components,

266 cytoskeletal and membrane traffic proteins, biological adhesion, development and signaling, and numerous

267 implicated pathways including synaptic vesicle trafficking. These results indicate that synaptic protein levels

268 were significantly altered in synaptosomes from *fam57b mut* larval brain synapses relative to AB.

269   We separately examined levels of synaptotagmin family members in brain synaptosome profiles and

270 found decreased Syt1 and Syt2a protein levels in *fam57b mut* compared to AB synaptosomes (**Fig. 7k**). This

271 interesting association between FAM57B regulation and Synaptotagmin expression (**Fig. 7e,f,h**) led us to

272 analyze further human SH-SY5Y isolated synaptosomes. We found a significant decrease in elongated SYT1

273 (ESYT1) in *FAM57B KO* compared to *FAM57B HET* and WT (**Fig. 7l**), a calcium activated synaptic protein

274 found to bind GLs (Yu et al., 2016). We then characterized hallmark proteins that function at the synapse from

275 brain synaptosomes, including synaptic vesicle fusion and tethering proteins. Bayés *et al.* previously examined

276 complexity of the adult zebrafish synapse proteome relative to adult mouse synapse proteome (Bayes et al.,

277 2017). As expected, not all synaptic proteins were detected at this immature stage of zebrafish development

278 compared to the adult brain. Enrichment of synaptic vesicle proteins including Syntaxins, Slc neurotransmitter

279 transporters, SNAPs, Stx/Vps, Synaptotagmins and membrane budding proteins including Dynamins and Rabs

280 verify synaptosome isolation and give new data regarding neuronal maturation in the zebrafish larval brain

281 (**Fig. 7j**). Comparison of synaptic protein profiles between genotypes demonstrated decreased vesicle fusion

282 and transport protein Nsfa, ligand-gated ion channel Si:ch211-251b21.1, and SNARE complex proteins Snphb,

283 Stx1b, Stxbp1a and Vamp3 (**Fig. 7j**). Together, these data show that synaptic proteins essential for vesicle

284 docking, exo- and endocytosis, including synaptotagmin family members, are diminished in synaptosomes

285 isolated from *fam57b mut* brains relative to AB, suggesting Fam57b is essential for synapse integrity.

286

287 **Depressed spontaneous electrical activity and response to stimuli in *fam57b* mutants**

8

288   To understand how changes in *fam57b* gene dosage impact neuronal activity, we tested brain activity

289   by electrophysiological analysis. We previously described a noninvasive electrophysiology technique that can

290   be used in live larvae to measure spontaneous activity in the brain and spinal cord (Tomasello and Sive, 2020).

291   Using a multielectrode array (MEA), we measured local field potential (LFP) parameters and relative

292   coordinated (network) activity in the brain of 7 dpf larvae (**Figs. 8a-c**). Larva were individually immersed in

293   precooled 1.5% low-melt agarose in E3 solution and mounted in a 64-electrode containing well. We measured

294   spontaneous brain activity over a 10-minute period, comparing *fam57b mut* to AB controls. Only electrodes in

295   contact with the larval head were analyzed, ~6 to 8 electrodes, whose signal was pooled. *fam57b mut* larvae

296   had slightly smaller heads than AB at 7 dpf (**Supp Fig. 7**, **Table S8 - Zebrafish Larvae Head and Body**

297   **Measurements)**, however these changes do not impact electrophysiological studies. Overall, *fam57b mut*

298   spontaneous brain activity was severely diminished relative to ABs. This included significant decrease in

299   number of LFPs, mean LFP rate, and inter-LFP-interval coefficient of variation measurements, indicating

300   decreased spontaneous brain activity with reduced kinetics (**Fig. 8a**). However, the decreased coefficient of

301   variation in the *fam57b mut* suggests LFP interval distributions are detected at a more regular rate. Measuring

302   electrographic bursts, at least 5 LFPs per 100 ms, we were unable to detect any burst activity under these

303   settings in the *fam57b mut*, while bursts were detected in ABs. To increase sensitivity for detection of burst

304   activity, we lowered the detection parameters to at least 3 LFPs per 200 ms (right column), and found

305   decreased electrographic burst duration, number of LFPs per burst, burst frequency and percentage in *fam57b*

306   *mut* relative to AB (**Fig. 8a**). In addition, we examined relative network activity, as defined by at least 3 LFPs

307   detected simultaneously between a minimum of two electrodes. Relative network activity was also significantly

308   decreased in *fam57b mut* compared to AB. Synchrony index of bursts did not change between the two

309   genotypes, indicating coordination of network activity did not differ. While LFP waveforms could not be

310   quantified due to small distance variations when mounting individual larva, we observed smaller relative

311   waveforms in *fam57b mut* compared to AB (**Fig.8c**), consistent with overall decreased brain activity in *fam57b*

312   *mut* larvae. A representative raster plot of LFP activity in the head region over the 10-minute recording period

313   illustrates the relative decrease in LFP propagation, burst and network detection measured (**Fig. 8d**). A

314   representative image of a mounted larva immersed in agarose on a 12-well 64 electrode plate is shown in **Fig.**

315   **8e**. These data demonstrate severely diminished spontaneous brain activity in *fam57b mut* relative to AB

316   wildtype larvae, and highlight a role for Fam57b in regulating brain function.

317   After identifying significantly diminished spontaneous brain activity in *fam57b mut* larvae, we examined

318   correlations with behavioral activity. We first tested light-responsive sensorimotor startle behavior (**Table S9 -**

319   **Zebrafish Larvae Light Startle Response Data)**. Startle response, as indicated by distance traveled, was

320   measured over a 70-min time-frame with light extinguished every 10 minutes for 5 seconds (Tomasello and

321   Sive, 2020). The startle response window was in total 30 seconds, including the stimulus. We found a

322   considerable decrease in response to each light stimulus in *fam57b mut* compared to AB (**Fig. 8f**). However,

323   movement measured previous to startle (first 10 min) and relative habituation after startle cue did not overall

9

324 differ between the genotypes, indicating there is no alteration in movement outside of the light stimulus, and no

325 visual deficit in *fam57b mut* larvae.

326   To examine brain specific activity, we investigated seizure susceptibility (**Table S10 - Zebrafish Larvae**

327 **Seizure Assay Data)**. Seizures are prevalent in individuals affected with 16pdel syndrome, and may result

328 from processes involving several neurotransmitter systems, including glutamatergic, cholinergic and

329 GABAergic (Mefford et al., 2011). To measure seizure propensity, larvae were immersed in pentylenetetrazol

330 (PTZ), a GABA$_A$ antagonist, well characterized for use in zebrafish (Baraban et al., 2005). After a 10-minute

331 baseline movement recording, two different concentrations of PTZ, or E3 media only control, were applied to

332 the individual well of each larva and recorded over 10 minutes. There was no significant change in normalized

333 movement, compared to baseline recording, in the absence of stimulus after addition of E3 (0 mM PTZ) control

334 between the *fam57b mut* and AB (**Fig. 8g**). Increasing the PTZ dose increased normalized distance traveled

335 for both genotypes, but the increase was not significant for AB between 0 and 0.5 mM PTZ as observed in

336 *fam57b mut.* At 5 mM, we observed significantly less distance traveled in the *fam57b mut* compared to AB.

337 However, the relative fold change between 0 and 5 mM was much higher in the *fam57b mut* (roughly 32-fold)

338 compared to AB (roughly 11-fold). To understand the contribution of Fam57ba and Fam57bb to the seizure

339 phenotype, we incrossed *fam57ba$^{+/-}$;fam57bb$^{+/-}$* animals and measured seizure propensity in resulting

340 genotypes (**Supp Fig. 8**). We found no statistical differences in baseline movement between AB control

341 compared to *fam57ba$^{-/-}$;fam57bb$^{-/+}$, fam57ba$^{-/+}$;fam57bb$^{-/+}$* nor *fam57ba$^{-/+}$;fam57bb$^{+/+}$*. The data are consistent

342 with increased movement after addition of 5 mM PTZ in *fam57ba$^{-/-}$;fam57bb$^{+/+}$* 7 dpf larvae compared to AB

343 control (McCammon et al., 2017). The enhanced PTZ-responsiveness of *fam57b mut* relative to WT suggests

344 that Fam57ba and Fam57bb function in GABA-mediated signaling with synergistic effects after the loss of

345 Fam57bb in combination with Fam57ba. These analyses indicate neuronal specific changes after loss of

346 *fam57b mut*, however, FAM57B is also expressed in muscle. We assessed neuromuscular junction

347 contribution by immunostaining, but did not observe differences between *fam57b mut* and AB (**Supp. Fig. 9**).

348 Together, altered brain activity, response to multiple stimuli including GABA$_A$ antagonist, and gross anatomical

349 differences including the corpus cerebelli (**Fig. 7f**), suggest changes to GABAergic network activity in the

350 developing *fam57b mut* brain.

351   In sum, there are significant behavioral changes in zebrafish larvae after *fam57b* loss of function. *fam*

352 *mut* larvae move similarly to AB over time without a stimulus. However, with a stimulus – either dark or PTZ

353 application, there is altered behavioral responsiveness relative to AB. These findings are consistent with

354 changes in brain activity in *fam57b mut* relative to AB controls.

355

Discussion

357   This study has uncovered alterations of lipid metabolism in iPSC differentiated cortical neurons derived

358 from people affected with 16pdel Syndrome, relative to unaffected. These 16pdel neurons display increased

359 excitability relative to controls, and show a sex-linked difference. Among the set of twenty-five 16pdel genes,

360 *FAM57B* is a key candidate gene linked to symptomatology, and implicated in lipid metabolism. Consistently,

361 we find changes in 16pdel neuronal lipids, as well as those in *FAM57B* mutants in a human neuronal cell line

362 and zebrafish model. In *FAM57B* mutants, lipid alterations occur concomitantly with alterations in membrane

363 architecture, synapse lipid composition synapse-associated proteins, and in zebrafish, altered brain activity

364 and behavior. Specifically, we identified altered abundance of the monoacyglyerol (MG) group in all

365 experimental conditions, including 16p11.2 deletion neurons and SH-SY5Y *FAM57B KO* intact neurons and

366 isolated synaptosomes (**Figs. 2a, 4a, 5f, 6a**). We do not know how these outcomes are linked, but it is

367 plausible that FAM57B acts through sphingolipid (SL) and glycerolipid (GL) regulation as the starting point for a

368 cascade of effects after loss of function. Dysregulated lipid metabolism has a multifaceted effect on neurons,

369 for example, increased lipid energy consumption escalates oxidative stress, promoting inflammation,

370 mitochondrial and metabolic dysfunction and excitotoxicity (Tracey et al., 2018). The saturation and length of

371 individual lipids affects their intracellular localization, impacting the cytoskeleton and lipid raft composition, so

372 disrupting signaling processes that regulate neurotransmitter synthesis and release, cytoskeletal integrity,

373 myelination and intracellular transport (Pike, 2003, Tracey et al., 2018). Abnormal cholesterol metabolism has

374 been observed in patients with Asperger syndrome and other ASDs, suggesting a correlation between lipid raft

375 formation and ASD (Dziobek et al., 2007, Tierney et al., 2006).

376 In contrast to a previous report (Yamashita-Sugahara et al., 2013), we find that FAM57B is not a

377 ceramide synthase (CerS) but rather is a modulator of CerS activity. Supporting a functional interaction

378 between FAM57B with CerS2 and CerS6, lipidomic profiling uncovered altered SLs and GLs integral to the

379 lipid membrane in *FAM57B* mutants of both zebrafish brain and a human neuronal cell line, also indicating

380 consistent activity of this gene across species. Comparing these mutants with 16pdel iPSC differentiated

381 patient neurons, we identified a consistent change in ether-linked phosphatidylethanolamine (PE) species,

382 supporting a role for *FAM57B* in the altered 16pdel lipidome relative to unaffected. However, some lipid groups

383 altered in mutant human neuronal cells, zebrafish brain and 16pdel neurons relative to controls are do not

384 overlap, suggesting additional genes regulate 16pdel lipid metabolites or that these result from other

385 differences between tissues being compared. Beyond *FAM57B,* multiple genes in the 16p11.2 interval encode

386 enzymes with predicted roles in metabolic processing or interconversion including *ALDOA, CDIPT, GDPD3,*

387 *BOLA2, SULT1A3, SULT1A4* and YPEL3 (Giannuzzi et al., 2019, Arbogast et al., 2016). Together with

388 FAM57B activity, this set of genes may function to modulate lipid metabolism.

389 Early in brain development, *fam57b* mutants displayed altered plasma membrane architecture, while in

390 more mature neurons, synaptic proteins were present at significantly diminished levels in synaptosomes

391 prepared from mutants relative to controls. One important affected protein in zebrafish brain was Syt1a, a

392 member of the Synaptotagmin family and calcium sensor SNARE binding complex protein that contributes to

393 synchronous synaptic vesicle release (Li et al., 2017). Baker-Gordon Syndrome, a SYT1-associated

394 neurodevelopmental disorder, maps to an autosomal dominant heterozygous mutation of *SYT1,* that is

395 associated with reduced neurotransmitter release (Baker et al., 2018). This association supports our previous

396 findings of a genetic interaction between *fam57ba* and *doc2a*, another 16p11.2 interval gene, encoding a

397 calcium sensor SNARE binding complex protein for spontaneous vesicle release, where double heterozygotes

398 showed hyperactivity and increased seizure propensity (McCammon et al., 2017). In further connections,

399 ESYT1 is a related Synaptotagmin family member whose synaptic levels were diminished in human neuronal

400 cell lines, that may play a role in cellular transport of PC, PE, PI, and translocates to sites of contact between

401 the presynaptic endoplasmic reticulum and the cell membrane in response to increased cytosolic calcium

402 levels (Yu et al., 2016). Neurotransmission is decreased in *Esyt D.melanogaster* mutants, with a proposed role

403 in synapse extension, highlighting the essential homeostasis of lipids at the synapse (Kikuma et al., 2017).

404   Diminished spontaneous brain activity and altered behavioral response after stimulation seen in *fam57b*

405 zebrafish mutants is consistent with alteration of brain synaptic composition. These studies suggest Fam57b is

406 essential early in development of the brain, and loss of *fam57b* leads to linked events starting with changes in

407 plasma membrane architecture followed by disturbance in protein organization at the membrane and

408 detriments to basic neuronal function that impacts brain activity and behavior. Together, we propose a model

409 whereby Fam57b functions to maintain normal plasma membrane physiology, necessary for proper formation

410 and function of neurons (**Fig. 8h**).

411   In a recent study that analyzed the largest ASD-associated exome sequence to date (Satterstrom et al.,

412 2019), 102 high risk genes were identified as tightly associated with ASD. In the analysis, a rare G:A mutation

413 was discovered in *FAM57B,* located in the 5'UTR of one *FAM57B* transcript isoform, and residing in the

414 promoter/enhancer region of the five other *FAM57B* isoforms. This synonymous mutation is predicted to create

415 binding sites for several transcription factors and may impact enhancer activity in neurons, affecting gene

416 expression (prediction with information from dbSNP, JASPAR, GTEx). The association of a single gene *FAM57B*

417 mutation with ASD outside of the complex CNV 16pdel gene cohort, encourages further evaluation of *FAM57B*

418 in brain development and function.

419   Correlating the multitude of symptoms to specific genes associated with a multigenic copy number

420 variant region is extremely challenging. Variation in clinical phenotypes of 16p11.2 deletion syndrome patients

421 further indicates the need to understand the biology of this CNV (Fetit et al., 2020). Previously, we identified

422 gene interactions among the 16p11.2 interval (McCammon et al., 2017) that do not converge on functional

423 networks predicted by ASD gene-set enrichment analysis by Pinto *et al.* (Pinto et al., 2010), suggesting indirect

424 mechanisms of genetic interaction. We investigated the interaction between *doc2a*, encoding for a synaptic

425 vesicle-associated calcium-binding protein, and *fam57ba*. Haploinsufficiency of this genetic interaction

426 identified both a body and central nervous system phenotype, including seizure activity. No evidence for

427 physical interactions between proteins encoded by 16p11.2 genes has been found (Lin et al., 2015). Along with

428 *DOC2A*, several genes within the interval are candidate contributors to neurodevelopment and

429 neuropsychiatric phenotypes, including *KCTD13, SEZ6L2, KIF22, MVP, TAOK2* and *QPRT*. In a functional

430 screen, we defined genetic interaction between *fam57ba, kctd13, sez6l2* and *kif22* (McCammon et al., 2017).

431 *KCTD13 encodes a ubiquitin ligase adaptor with cognitive defects identified in mice heterozygous for the gene*

432 (Chen et al., 2009, Golzio et al., 2012, Martin Lorenzo et al., 2021). KIF22 is a kinesin-like protein necessary

433 for embryonic chromosome segregation and axonal branching patterns (Park et al., 2016, Antonio et al., 2000,

434 Ohsugi et al., 2008). SEZ6L2 has been connected to seizure activity and modulates neurite outgrowth (Boonen

435 et al., 2016). MVP can function as a regulator of the homeostatic component of experience-dependent

436 behavior (Ip et al., 2018). *TAOK2* encodes a serine/threonine kinase that can play a role in dendrite formation

437 (de Anda et al., 2012). *QPRT* encodes quinolinate phosphoribosyltransferase that catabolizes quinolinic acid,

438 whose elevation has been linked to epilepsy and has also showed regulation by ASD candidate genes

439 (Chiocchetti et al., 2016, Haslinger et al., 2018). The strong genetic interaction between *FAM57B* and most of

440 the above-described genes highlights the connection between lipid regulation and brain development or

441 maturation. Although *FAM57B* haploinsufficiency alone cannot account for the multitude of disrupted

442 biochemical and cellular properties in 16pdel affected neurons, disrupted lipid metabolism is tightly correlated

443 to 16pdel Syndrome. The insight into lipid alterations and a potential role for *FAM57B* in mediating these

444 changes, gives a new view of mechanisms underlying 16pdel Syndrome, and holds promise for new

445 therapeutic directions.

446

447 **Limitations of the Study**

448 In the large 16p11.2 copy number variant interval, haploinsufficient symptoms do not resolve to a single causal

449 gene. *FAM57B* interacts genetically with many other 16p11.2 interval genes and is a strong candidate for

450 contribution to symptomatology. We studied the poorly defined function of FAM57B to understand its role in

451 lipid regulation and function in the brain. *FAM57B* mutant neuronal lines do not recapitulate all phenotypes

452 associated with 16p11.2 deletion syndrome neurons. For instance, the *FAM57B* heterozygote SH-SY5Y

453 differentiated neurons and zebrafish brains do not show exactly the same lipid profiles as neurons derived from

454 16p11.2 deletion iPSC, although there is overlap. Since 16pdel syndrome results from changes in gene

455 dosage through haploinsufficiency, rescue of FAM57B levels must be precise to match endogenous levels to

456 avoid spurious gene dosage effects. However, in the 16p11.2 chromosomal deletion, the *FAM57B* promoter

457 and enhancer regions are also deleted, it is not an easy task to rescue FAM57B expression to endogenous

458 levels. The nature of the copy number variant phenotype indicates that exogenous expression to rescue

459 FAM57B could result in outcomes modulated by dosage, and that the entire gene with its regulatory regions

460 would have to be used for rescue. The *FAM57B* regulatory regions have not been mapped, and so are not

461 available for rescue constructs.

462

463 **Acknowledgements**

479

Author Contributions

481   DLT and HS designed the study, interpreted results and wrote the manuscript. AHF helped conceive,

482   supervise, interpret and write the CerS study (**Fig. 3**). JK and YK performed the experiments in **Fig. 3**. JMM

483   created the *fam57b mutant* zebrafish line. MM and RJ instructed on stem cell culture work and provided

484   unaffected control iPSC (originally from Coriell Institute Biobank). DLT performed all other studies.

485

Resource Availability

493   *Lead Contact*

494   Further information and requests for resources and reagents should be directed to and will be fulfilled by the

495   lead contact, Hazel Sive (h.sive@northeastern.edu).

496   *Materials Availability*

497   pcDNA3.1 FAM57B and CerS constructs, SH-SY5Y *FAM57B HET* and *FAM57B KO*, and Zebrafish lines

498   *fam57ba$^{+/-}$;fam57bb$^{+/-}$* and *fam57ba$^{-/-}$;fam57bb$^{-/-}$* created in this manuscript are available upon request from

499   lead contact.

500 *Data Availability*

501 • The authors declare that all data supporting the findings of this study are available within the article and
502 its supplementary information.

503 • Raw data, including proteomics and lipidomics results, are available in the Supplemental Excel
504 spreadsheet. Additional data can be requested from lead contact.

505 • Any additional information required to reanalyze the data reported in this paper is available from the
506 lead contact upon request.

507 **Experimental model and subject details**

508

509 **Animal Model**

510 Adult zebrafish of the wildtype AB strain were maintained at 28˚C on 12h/12h light/dark cycle. Embryos were

511 obtained from natural spawning and staged as previously described by Kimmel *et al.* (Kimmel et al., 1995).

512 Due to the polygenic nature of sex determination and timing of gonadal development in zebrafish, we are

513 unable to determine the sexes of the embryos and larvae for our assays. However, because our assays

514 utilized large numbers of embryos and larvae, both sexes should be adequately represented. Embryos were

515 obtained from separate crosses of *fam57b mut* mutant fish. *fam57b het* fish were generated by crossing

516 *fam57b mut* to AB fish. The MIT Committee on Animal Care approved animal experimentation under protocol

517 0417-036-20. The Whitehead Institute Biosafety Committee approved of all materials under protocol HS001.

518 All experiments conform to the relevant regulatory standards.

519

520 *fam57ba*[-/-] mutants were injected with *fam57bb* targeted sgRNA at 1 - 4 cell stage, previously described in

521 McCammon *et al.* CRISPR/Cas9 induced mutation resulted in 17 bp deletion and early stop codon.

522 Experiments were performed after 4 generations of crosses with AB controls.

523 fam57bb 5' to 3' TAGGTGATGTCCTGGCAGGAAG

524 fam57bb 3' to 5' AAACCTTCCTGCCAGGACATCA

525 For genotyping, PCR amplified region of in/del. PCR was digested with EarI restriction enzyme, with

526 homozygous mutation detected by loss of EarI restriction site. *fam57b mut* line was outcrossed with AB

527 periodically to avoid chromosomal abnormalities.

528

529 **Generation and characterization of iPSC lines**

530 Unaffected control male and female iPSC lines, 599 and 657, were a generous gift from Rudolf Jaenisch,

531 originally obtained as fibroblasts from Coriell Institute Biobank. iPSC of 16p11.2 deletion carriers were obtained

532 from Simons Variation in Individuals Project (Supplemental Table 1) (Simons Vip, 2012). Cell line corresponds

533 to subjects with abbreviated ID from RUCDR. Acquisition of lines were in consideration of potential sex

534 differences in 16pdel syndrome. All iPSCs were tested for negative mycoplasma and normal karyotype.

15

535 Cytogenetic analysis was performed on twenty G-banded metaphase cells at Cell Line Genetics. All

536 experiments involving cells from human donors were performed in compliance with established IRB protocols

537 at the Whitehead Institute. The Whitehead Institute for Biomedical Research and MIT Biosafety Committees

538 approved safety considerations around the experiments performed.

539

540 *iPSCs* - Cells were cultured on plates coated with Matrigel (Corning #CB-40234A) in mTeSR+ media

541 (STEMCELL Technologies #85850) with pen/strep. Y27632 (STEMCELL Tech #72302) was added to cells

542 prior to passaging (single colonies), then passaged with ReLeSR or Accutase for single colonies (STEMCELL

543 Technologies #05872 and #07922). Cells were maintained at 37°C with 5% O_2.

544

545 *Generation of Cortical Neurons* - iPSCs were differentiated into neural progenitor cells (NPCs) by FGF

546 exchange. FGF was slowly removed by exchanging mTeSR+ with -FGF media (DMEM/F12/HEPES (Thermo

547 Fisher Scientific #12400024), Neurobasal (Thermo Fisher Scientific #21103049), N2 (Gibco #17502048),

548 Gem21 (GeminiBio #400-160) MEM non-essential amino acids (NEAA) (Thermo Fisher Scientific #11140050),

549 GlutaMAX (Gibco #35050061), pen/strep, D(+) Glucose and NaCl) every day over 2 - 3 weeks. When rosettes

550 were present, media was exchanged with +FGF media (DMEM/F12/HEPES, Neurobasal, N2, Gem21 -

551 Vitamin A (GeminiBio #400161), MEM NEAA, GlutaMAX, pen/strep, Beta-Mercaptoethanol (Sigma-Aldrich

552 #M3148) and 4 ng/mL FGF (Peprotech #100-18B)) plus 2.5 µM/mL dorsomorphin (Tocris #3093). Cells were

553 incubated with Y27632 before passaging with Accutase, expanded and passaged at least 3 times until

554 homogeneous NPC culture. NPCs were passaged on poly-D-lysine (Thermo Fisher Scientific #A3890401) and

555 laminin (Sigma-Aldrich #L2020) coated plates for cortical neuron differentiation. NPCs media was exchanged

556 with Neuronal Differentiation media (Neurobasal, GlutaMAX, NEAA, D(+) Glucose, Gem21, Culture One

557 (Gibco #A3320201), 5 µg/mL BDNF and GDNF (Peprotech #450-02 & #450-10), pen/strep) for 1 month,

558 changing media every 2 to 3 days. Cells were maintained at 37°C under normoxic conditions.

559

560 **Generation and characterization of SH-SY5Y Neuroblastoma cell line**

561 SH-SY5Y cells, originally from ATCC, were a kind gift from David Bartel, Whitehead Institute for Biomedical

562 Research. Cells were maintained in EMEM (ATCC # 30-2003), F12 (ATCC # 30-2006) media supplemented

563 with fetal bovine serum (FBS Sigma-Aldrich #12306C) and pen/strep in a 37˚C incubator with 5% CO_2.

564 Differentiation of cells to neuronal model were induced with media containing Neurobasal, Gem21, GlutaMAX,

565 All-trans-retinoic acid (Sigma-Aldrich # R2625) and pen/strep, for 4 days in dark to prevent retinoic acid

566 degradation from light exposure (Kovalevich J, 2013).

567

568 CRISPR sgRNA designs were identified from Target Guide Sequence Cloning Protocol, Zhang lab, with

569 sequence overlapping the TLC domain of FAM57B (Cong et al., 2013). 10 targeted guides to FAM57B

570 sequence were individually transformed in pLC OPTI-Stuffer plasmid, a kind gift from David Sabatini,

571 Whitehead Institute, and lentivirus was grown in HEK293T cells. Generation of CRISPR/Cas9 induced

572 mutations via lentiviral transduction was performed according to Wang *et al.* protocols (Wang et al., 2014,

573 Wiles et al., 2015). After puromycin selection, cells were gently triturated and diluted to approximate 1 cell per

574 well in 96 well plate. Wildtype cells were simultaneously single cell diluted and sorted to serve as additional

575 control for experiments. Incorporation of mutation was determined by Next Generation Sequencing.

576

577 FAM57B Homozygote deletion (KO)

578 sgFAM57B1 5' to 3' - GGTGCTCCACCATGCCGCCA

579 Mutation resulted in frameshift with 111 and 121 bp deletion on either strand, resulting in early stop codon.

580

581 FAM57B Heterozygote deletion (HET)

582 sgFAM57B2 5' to 3' - GGGCACAGCAAATTGCGTGT

583 Mutation resulted in frameshift with 20 bp deletion on one strand, resulting in early stop codon.

584

585 Adeno-Associated Virus Integration Site 1 (AAVS1) targeted control

586 sgAAVS1 5' to 3' - CACCGGGGCCACTAGGGACAGGAT

587 Mutation resulted in frameshift and 51 bp and 1 bp deletion on either stand, resulting in early stop codon. The

588 AAVS1 served as a control for all SH-SY5Y experiments. WT was compared to AAVS1 to determine

589 confidence of statistical significance when compared to *FAM57B HET* and *KO*.

590 **Method Details**

591 **HEK293 Cell Culture and Co-Immunoprecipitation**

592 HEK293T cells were cultured in Dulbecco's modified Eagle's medium (Corning # MT15017CV) supplemented

593 with 10% fetal bovine serum, 100 IU/ml penicillin, 100 μg/ml streptomycin, and 110 μg/ml sodium pyruvate.

594 Transfections were performed with the polyethylenimine reagent (Sigma-Aldrich # 08719) using 8 μg of

595 plasmid per 10 cm culture dish for 36–48 h; medium was exchanged after 6 hours. pcDNA3.1 was used as a

596 control. DYKDDDDK (Flag)-tagged human FAM57B plasmid (sequence sent to Genscript and available upon

597 request). Hemagglutinin (HA)-tagged human CerS plasmids were generated as described (Laviad et al., 2012).

598 Co-immunoprecipitation was performed using cells transfected with a variety of plasmids in pcDNA3.1-C-DYK

599 or pcDNA3.1-C-HA (sequences sent to Genscript and available upon request). HA-tagged CerSs were used to

600 confirm non-specific binding to Flag affinity resins. Cells were washed twice with cold PBS and lysed in lysis

601 buffer (20 mM Tris (pH 7.4), 150 mM NaCl, 1 mM EDTA, 1% NP-40, 5% glycerol and protease inhibitor

602 (Sigma-Aldrich #200-664-3)). Lysates were incubated on ice for 10-15 min. Protein was determined using the

603 BCA reagent. FLAG-tagged human FAM57B, using an anti-FLAG affinity resin (Genscript #L00432). Lysates

604   were incubated with 40 µl of beads overnight at 4°C with rotation. The resin was washed three times in 1 ml of

605   lysis buffer at 4°C with rotation. Proteins were eluted using 4X SDS sample buffer (BioRad #161-0747). Eluted

606   proteins were analyzed by Western blotting for detection of HA-tagged interacting proteins.

607

608   **Ceramide Synthase Assays**

609   Cell homogenates were prepared in 20 mM HEPES-KOH, pH 7.2, 25 mM KCl, 250 mM sucrose, and 2 mM

610   MgCl2 containing a protease inhibitor mixture. Protein was determined using the BCA reagent (Thermo Fisher

611   Scientific). Samples were incubated with 15 µM NBD-sphinganine (Avanti Polar Lipids # 810206P), 20 µM

612   defatted BSA (Sigma-Aldrich #10775835001), and 50 µM 16- or 24-fatty acyl-CoA (Avanti Polar Lipids 870743

613   & 870725) in a 20 µl reaction volume. CerS (40 µg protein, 25 min reaction time) was assayed using C24.1-

614   CoA and Cer5/6 (5 µg protein, 5 min reaction time) assayed using C16-CoA. Reactions were terminated by

615   chloroform/methanol (1:2, v/v) and lipids extracted. Lipids were dried under N_2, resuspended in

616   chloroform/methanol (9:1, v/v), and separated by thin layer chromatography using chloroform/methanol, 2M

617   NH4OH (40:10:1, v/v/v) as the developing solvent. NBD-labeled lipids were visualized using an Amersham

618   Typhoon5 imager and quantified by ImageQuantTL (GE Healthcare, Chalfont St Giles, UK). All solvents were

619   of analytical grade and were purchased from Bio-Lab (Jerusalem, Israel).

620

621   **Sample Collection for Lipidomics**

622   *iPSC Differentiated Neurons* - 2 x 10^6 NPCs were plated in 6 well plate, at least 3 wells per genotype.

623   Differentiation to cortical neurons was performed as stated above. Cells were washed with phosphate buffered

624   saline solution (PBS). Cells were scraped in LC grade methanol and homogenized in eppendorf tube

625   containing water and LC grade chloroform with pestle mixer, followed by vortexing for 10 minutes at 4°C. Lipids

626   were separated by centrifuging top speed at 4°C. This was repeated three times with all samples run together

627   in positive ion mode for lipidomic analysis. Raw data are provided in the Supplemental Excel spreadsheet.

628

629   *Differentiated SH-SY5Y Cells* - 1 x 10^6 cells were plated per well in 6 well plate, 3 wells per genotype. SH cells

630   were differentiated over 4 days in media containing retinoic acid. Cells were washed with PBS. Cells were

631   scraped in LC grade methanol and homogenized in eppendorf tube containing water and LC grade chloroform

632   with pestle mixer, followed by vortexing for 10 minutes at 4°C. Lipids were separated by centrifuging top speed

633   at 4°C. This was repeated twice with all samples run together. Raw data are provided in the Supplemental

634   Excel spreadsheet.

635

636   *Zebrafish* - At 7 dpf, larvae were deeply anesthetized with tricaine. Brains with surrounding epidermal layer

637   were dissected and flash frozen on dry ice. Collections were pooled at 20 brains per sample. Brains were

638   homogenized in an eppendorf tube with a pestle mixer in LC grade methanol, LC grade chloroform and water,

639   followed by vortexing for 10 minutes at 4°C. Lipids were separated by centrifuging top speed at 4°C. Brains

640 were collected and stored in -80°C over many dissections to acquire adequate tissue for analysis. This was

641 repeated twice per genotype, with the *fam57b mut* and AB cohort run at different times (different normalization)

642 while the *fam57b het* and AB cohort were run at the same time. Raw data are provided in the Supplemental

643 Excel spreadsheet.

644

645 **Untargeted Lipidomics**

646 Lipids were separated on an Ascentis Express C18 2.1 x 150 mm 2.7 um column (Sigma-Aldrich) connected to

647 a Vanquish Horizon UPLC system and an ID-X tribrid mass spectrometer (Thermo Fisher Scientific) equipped

648 with a heated electrospray ionization (HESI) probe. External mass calibration was performed using the

649 standard calibration mixture every seven days. Dried lipid extracts were reconstituted in 50 uL 65:30:5

650 acetonitrile: isopropanol: water (v/v/v). Typically, 2 uL of sample were injected onto the column, with separate

651 injections for positive and negative ionization modes. Mobile phase A in the chromatographic method consisted

652 of 60:40 water: acetonitrile with 10 mM ammonium formate and 0.1% formic acid, and mobile phase B

653 consisted of 90:10 isopropanol: acetonitrile, with 10 mM ammonium formate and 0.1% formic acid. The

654 chromatographic gradient was adapted from Hu *et al.* 2008 (Hu et al., 2008) and Bird *et al.* 2011 (Bird et al.,

655 2011). Briefly, the elution was performed with a gradient of 40 min; during 0−1.5 min isocratic elution with 32%

656 B; from 1.5 to 4 min increase to 45% B, from 4 to 5 min increase to 52% B, from 5 to 8 min to 58% B, from 8 to

657 11 min to 66% B, from 11 to 14 min to 70% B, from 14 to 18 min to 75% B, from 18 to 21 min to 97% B, during

658 21 to 35 min 97% B is maintained; from 35−35.1 min solvent B was decreased to 32% and then maintained for

659 another 4.9 min for column re-equilibration. The flow rate was set to 0.260 mL/min. The column oven and

660 autosampler were held at 55°C and 15°C, respectively. The mass spectrometer parameters were as follows:

661 The spray voltage was set to 3.25 kV in positive mode and 3.0 kV in negative mode, and the heated capillary

662 and the HESI were held at 300°C and 375°C, respectively. The S-lens RF level was set to 45, and the sheath

663 and auxiliary gas were set to 40 and 10 units, respectively. These conditions were held constant for both

664 positive and negative ionization mode acquisitions. The mass spectrometer was operated in full-scan-

665 ddMS/MS mode with an orbitrap resolution of 120,000 (MS1) and 30,000 (MS/MS). Internal calibration using

666 Easy IC was enabled. Quadrupole isolation was enabled, the AGC target was 1×10^5, the maximum injection

667 time was 50 msec, and the scan range was m/z = 200-2000. For data-dependent MS/MS, the cycle time as 1.5

668 sec, the isolation window was 1, and an intensity threshold of 1×10^3 was used. HCD fragmentation was

669 achieved using a step-wise collision energy of 15, 25, and 35 units, and detected in the orbitrap with an AGC

670 target of 5×10^4 and a maximum injection time of 54 msec. Isotopic exclusion was on, a dynamic exclusion

671 window of 2.5 sec was used, and an exclusion list was generated using a solvent bank.

672

673 High-throughput annotation and relative quantification of lipids was performed using LipidSearch v4.2.21

674 (Thermo Fisher Scientific/ Mitsui Knowledge Industries) using the HCD database (Taguchi and Ishikawa, 2010,

675 Yamada et al., 2013). LipidSearch matches MS/MS data in the experimental data with spectral data in the

19

676 HCD database. Precursor ion tolerance was set to 5 ppm, product ion tolerance was set to 10 ppm.

677 LipidSearch nomenclature uses underscores to separate the fatty acyl chains to indicate the lack of *sn*

678 positional information. In cases where there is insufficient MS/MS data to identify all acyl chains, only the sum

679 of the chains is displayed. Following the peak search, positive and negative mode data were aligned together

680 where possible and raw peak areas for all annotated lipids were exported to Microsoft Excel and filtered

681 according to the following predetermined quality control criteria: Rej ("Reject" parameter calculated by

682 LipidSearch) equal to 0; PQ ("Peak Quality" parameter calculated by LipidSearch software) greater than 0.75;

683 CV (standard deviation/ mean peak area across triplicate injections of a represented (pooled) biological

684 sample) below 0.4; R (linear correlation across a three-point dilution series of the representative (pooled)

685 biological sample) greater than 0.9. Typically, ~70% of annotated lipids passed all four quality control criteria.

686 Redundant lipid ions (those with identical retention times and multiple adducts) were removed such that only

687 one lipid ion per species/ per unique retention time is reported in merged alignments. For data where positive

688 and negative mode data were aligned separately some redundancies may still exist. Raw peak areas of the

689 filtered lipids were normalized to total lipid signal (positive or negative ionization mode) in each sample to

690 control for sample loading. Data presented are shown as Log$_2$FC compared to wildtype/control samples.

691 Statistics were performed in Prism, with each run analyzed separately.

692

693 **Zebrafish brain staining and imaging**

694 For 24 hours post-fertilization staining, embryos were deeply anesthetized in tricaine after being

695 dechorionated. Embryos were places into wells in 1% Agarose dishes. 1 ng Cholera Toxin subunit B (CT-B)

696 (Recombinant Alexa Fluor 488 conjugate, Invitrogen #C34775) was injected into the hindbrain ventricle

697 (Gutzman and Sive, 2010). Embryos were washed with E3 and incubated for 1 hour to allow CT-B binding.

698 Embryos were then fixed in fresh 4% PFA in phosphate buffered solution (PBS) overnight at 4°C. Embryos

699 were washed in PBS + Tween-20 (PBT) and incubated with 555-Phalloidin (Invitrogen #A34055) for 1 hour.

700 Alternatively, embryos were incubated with Duramycin-Cy3 conjugate (Molecular Targeting Technologies #D-

701 1006) PE stain for 45 min. Embryos were washed in PBT and mounted in DAPI Antifade (Thermo Fisher

702 Scientific #P36931) overnight. Imaging was performed on an inverted Zeiss LSM700 Laser Scanning Confocal

703 and processed on Fiji (ImageJ). CT-B and Duramycin images were processed on ImageJ to measure relative

704 puncta from staining. Particles were measured after drawing a size circle in each hemisphere comparing AB to

705 *fam57b mut* embryos. Threshold was set to intermodes to assume for bimodal histogram, particle size set

706 between 0 – 2 μm^2.

707

708 For 7 dpf larvae, the following protocol was adapted from the mouse protocol provided by LifeCanvas

709 Technologies (SHIELD kit, LifeCanvas Technologies). At 7 dpf, zebrafish were collected into Eppendorf tubes,

710 25 zebrafish per tube and anesthetized on ice briefly. Embryo buffer E3 was removed and replaced with 1 mL

711 SHIELD Perfusion Solution with diluted 4% paraformaldehyde (PFA) (Electron Microscopy Sciences # 50-980-

712 495), shaking overnight at 4°C. Whole zebrafish brains were dissected the next day and placed into tubes with

713 fresh SHIELD Perfusion Solution, shaking overnight at 4°C. Tissue was placed into 1 mL SHIELD OFF

714 solution, shaking overnight at 4°C. Tissue was transferred into SHIELD ON Buffer, shaking overnight at 37°C

715 in MaxQ 4450 (ThermoFisher Scientific). Tissue was then cleared with 1 mL passive clearing protocol using

716 SDS Clearing Solution, shaking for 5 days at 45°C. Clearing solution was washed off with 1 mL PBS + 1%

717 Triton-X (PBT) with 0.02% Sodium Azide 3 times over 24 hours shaking at 37°C. Tissue was blocked in 1 mL

718 PBT + 1% BSA for 2 hours shaking at room temperature, then incubated in primary antibody, shaking

719 overnight at 4°C. Antibodies: 1:100 Synaptotagmin-1 (Lifespan Bioscience # LS-B12889), GAD65 + GAD67

720 (Abcam #ab11070), Beta-Actin (Proteintech 60008-1) and 1:500 DAPI (Life Technologies # D1306), in 0.5 mL

721 PBT + 1% BSA. Primary antibody was washed off 3 times in PBT and incubated in secondary antibody

722 shaking overnight at 4 °C (1:500 488- 555- 680-conjugated antibodies (Jackson ImmunoResearch, 488 anti-

723 goat #805-545-180, 488 anti-mouse #715-545-151, 594 anti-mouse #715-585-150, 594 anti-rabbit #711-585-

724 152, anti-mouse 680 #715-625-150, anti-rabbit 680 #711-625-152) in PBT + 1% BSA). Secondary was washed

725 off 3 times in PBT, then 1 mL EasyIndex was added to tissue, shaking overnight at room temperature. Whole

726 brains were mounted in fresh EasyIndex on slides, placing coverslip with vacuum grease. Imaging was

727 performed on an inverted Zeiss LSM700 Laser Scanning Confocal and processed on Fiji (ImageJ).

728

PH3 Staining

730 At 24 hpf, *fam57b mut* and AB embryos were dechorionated and fixed overnight at 4°C in paraformaldehyde.

731 Embryos were washed with phosphate buffered saline with Tween-20 (PBT) and yolk sac was removed.

732 Embryos were incubated with 10% H_2O_2 for 1.5 hrs, then washed in PBT. Embryos were blocked in PBT with

733 bovine serum albumin at room temp for 4 hrs, then incubated with α-PH3 antibody (1:1000, Upstate

734 Biotechnology #06-570) overnight at room temp. Embryos were washed with PBT and incubated with

735 secondary antibody (1:500 goat α-rabbit IgG HRP, Invitrogen #31460) in PBT overnight at room temp.

736 Embryos were washed in PBT and flat mounted on glass slide with propidium iodide in glycerol. Imaging was

737 performed on a confocal microscope.

738

TUNEL Staining

740 Embryos were collected, fixed and processed as PH3 staining. Embryos were then dehydrated then

741 rehydrated interchanging ethanol and PBT. Proteinase K (Invitrogen # EO0491) was incubated in PBT on

742 neutator, then rinsed in PBT. TdT labeling was followed per manufacturer's instructions, ApopTag kit

743 (Chemicon # S7101). α-DIG (1:100, Thermo Fisher Scientific #700772) was used to detect the DIG labeled

744 ends. Embryos were washed in PBT and flat mounted on glass slide with propidium iodide in glycerol. Imaging

745 was performed on a confocal microscope.

746

Immunocytochemistry

21

748   Patient derived neurons were washed with PBS and fixed in fresh 4% paraformaldehyde in PBS overnight

749   rocking at 4°C. Cells were washed with PBT and blocked in PBT + BSA for 1 hour at room temperature.

750   Primary antibody was added to PBT overnight rocking at 4°C. Antibodies: 1:100 Syt-1, Vesicular Glutamate 1

751   and 2 (VGlut1/2, Synaptic Systems #135503) or Postsynaptic Density 95 (PSD95, Abcam #ab18258),

752   Acetylated-Tubulin (Ac-Tubulin, Abcam #ab179513). Primary antibody was washed off 3 times in PBT and

753   incubated in secondary antibody shaking overnight at 4°C (1:500 488- 555- 680- (Jackson ImmunoResearch,

754   see above) in PBT + BSA). Secondary was washed off 3 times in PBT, rocking for 2 hours at room

755   temperature. Cells were washed 3 times in PBT and mounted on slides with DAPI (Prolong Gold Antifade with

756   DAPI (Life Technologies #P36935). Imaging was performed on an inverted Zeiss LSM700 Laser Scanning

757   Confocal and processed on Fiji (ImageJ).

758

759   SH-SY5Y cells were plated on coverslips and differentiated over 4 days with retinoic acid medium. The same

760   imaging protocol was performed as above. Antibody: 1:200 Beta-Actin.

761

762   **Western blot**

763   HEK293T studies - Proteins were separated by SDS-PAGE and transferred to nitrocellulose membranes. HA-

764   tagged constructs were identified using antibodies against HA or Flag peptides (1:5,000, Abcam #ab18181,

765   #ab1162), and goat anti-rabbit or mouse horseradish peroxidase (1:10,000, #323-001-021, #223-005-024)

766   were used as secondary antibodies (Jackson). Equal loading was confirmed using a mouse anti-GAPDH

767   (Abcam #ab8245). Detection was performed using the ECL detection system.

768

769   Larvae brain tissue (25 larvae brains pooled per sample) or differentiated SH-SY5Y cells (1×10^6 cells per

770   sample) were washed with PBS then lysed in RIPA buffer (Thermo Fisher Scientific #89900) with protease

771   inhibitor cocktail with a pestle homogenizer. Tissue/cells were rotate at 4°C for 30 min, then spun full speed 10

772   min. The supernatant was removed containing proteins, with denature in laemmli buffer for 1 hr at RT. Protein

773   was separated on 10-40% gel and transferred PVDF by wet transfer. Membranes were blocked in 5% dry milk

774   in TBS + Tween 20. Primary antibody was incubated overnight. Same antibodies were used for

775   immunofluorescence and western analysis. Antibodies: Syt-1, Beta-Actin, GAPDH), FAM57B (Proteintech

776   20760-1-AP). Secondary antibodies 1:2000 IRDye (Li-Cor 800CW Rabbit #92632211, 680RD Mouse

777   #92668070) were incubated for 1 hour at room temperature. Blots were imaged and quantified on a Li-Cor

778   Odyssey.

779

780   **Biotinylation and MS/MS**

781   At 7 dpf, larvae were deeply anesthetized with tricaine. Larvae were dissected in PBS with protease inhibitor

782   cocktail on ice, pooling 20 brains per genotype per sample. Assay was performed according to protocol

783   utilizing Pierce Cell Surface Protein Isolation Kit (Thermo Fisher Scientific #89881) with the following

784 modifications. 1 vial of biotin was resuspended in 2 mL PBS and fresh brains were incubated with 1 mL

785 biotin/PBS solution rotating for 45 minutes at 4C. Elution of biotin-bound proteins in water + DTT 1 hour at

786 room temperature. Eluates were reduced, alkylated and digested with trypsin at 37°C overnight. This solution

787 was subjected to solid phase extraction to concentrate the peptides and remove unwanted reagents. Solution

788 was injected onto a Waters NanoAcquity HPLC equipped with a self-packed Aeris 3.6 μm C18 analytical

789 column 0.075 mm by 20 cm, (Phenomenex). Peptides were eluted using standard reverse-phase gradients.

790 The effluent from the column was analyzed using a Thermo Orbitrap Elite mass spectrometer (nanospray

791 configuration) operated in a data dependent manner for 54 minutes. The resulting fragmentation spectra were

792 correlated against the known database using Mascot (Matrix Science). Scaffold Q+S (Proteome Software) was

793 used to provide consensus reports for the identified proteins. PEAKS Studio 8.5 was used for data analysis as

794 a supplement to Mascot. Raw data are provided in the Supplemental Excel spreadsheet.

795

796 **Synaptosome Isolation**

797 7 dpf zebrafish larvae were anesthetized in Tricaine with larvae buffer E3. Whole brains were dissected from

798 the larvae and placed into a 1.5 mL Eppendorf tube on ice, pooling 20 brains per genotype. The tissue was

799 centrifuged at top speed and excess liquid was removed. 200 μl of SYN-Per Reagent (Thermo Fisher

800 Scientific #87793) plus protease cocktail inhibitor was added to the eppendorf on ice. With a pestle, the brains

801 were homogenized with 10 strokes and the tube was gently turned 3 times to dissociate cells. The tissue was

802 centrifuged at 1200 x G for 10 min at 4°C. The supernatant was collected and added to a new Eppendorf tube.

803 The sample was centrifuged at 15,000 x G for 20 min at 4°C. The supernatant was removed and the pellet was

804 gently resuspended in 100 μl of SYN-Per Reagent plus protease cocktail inhibitor. The samples were flash

805 frozen and processed for tandem mass spectrometry (MS/MS) after reducing alkylating and digesting with

806 trypsin as indicated above.

807

808 SH-SY5Y cells were plated at 1 x 10^6 per well in 6 well plates, with 1 well per independent sample for all

809 genotypes. After 4 days differentiation, cells were washed with PBS plus protease inhibitor cocktail. Cells were

810 scraped in the same solution and centrifuges in 1.5 mL Eppendorf tube at top speed for 30 seconds at 4°C.

811 The wash was removed and the same protocol was used as for larval brain synaptosome isolation. After

812 samples were flash frozen, they were then processed for MS/MS or LC/MS analysis. Raw data are provided in

813 the Supplemental Excel spreadsheet.

814

815 **Electrophysiology**

816 iPSC Differentiated Neurons - 1 x 10^4 NPCs were plated and matured over 1 month in a PDL and Laminin

817 coated 48-well CytoView plate (Axion Biosystems # M768-tMEA-48B). Recordings of spontaneous activity

818 were taken over 10-minute periods on the Maestro system (Axion Biosystems). AxIS software compiled the

819 data collected from recordings. Data were collected for LFPs (firing frequency in Hz), electrographic burst

820 events (minimum 5 LFPs/100 ms) and relative network activity (minimum 3 LFPs detected simultaneously

821 between a minimum of two electrodes). LFP detection was filtered at 6 × standard deviation to remove potential

822 artifacts. The external physiological solution contained (in mM) 128 NaCl, 5 KCl, 2 CaCl$_2$, 1 MgCl$_2$, 25 HEPES

823 and 30 glucose, pH 7.3, Osmolarity 315 - 325. The High KCl solution contained (in mM) 63 NaCl, 70 KCl, 2

824 CaCl$_2$, 1 MgCl$_2$, 25 HEPES and 30 glucose, pH 7.3, Osmolarity 315 - 325.

825

826 Live larvae MEA recordings were performed as detailed in Tomasello and Sive 2020 (Tomasello and Sive,

827 2020). For these recordings, larva was immersed in low-melt agarose in 12-well 64 electrode Cytoview plates

828 (Axion Biosystems (discontinued, recommend 6-well plate)). LFP activity was recorded for 10 minutes, noting

829 the electrodes in contact with larva head region. Larva were immediately sacrificed after recordings. Data was

830 processed with AxIS and Axion Neural Metric Tool (Axion Biosystems).

831

832 **Larval Behavior**

833 At 7 dpf, dishes containing larvae were moved to the bench to allow acclimation to RT. For experimentation,

834 only larvae with an inflated swim bladder and no other morphology phenotypes, such as a crooked tail, were

835 selected. With a cut 200 µl tip, larvae were individually pipetted into 96-well plates with 200 µl E3 media and

836 moved to the Noldus Daniovision for 10 min habituation period. The larvae were exposed to a testing period of

837 70 minutes, with light (at 10%) extinguished for 5 seconds at 10-minute intervals. Point tracking collected

838 distance and velocity traveled. Distance moved was calculated using the Ethovision XT 11 software from

839 Noldus. Raw data are provided in the Supplemental Excel spreadsheet.

840

841 The same method is performed as above up to habituation. Baseline activity was then recorded for 10 minutes,

842 followed by exchange of 100 µl E3 from each well with 100 µl of varying concentrations of PTZ to test a range

843 of doses. Plates were immediately placed back on the Daniovision system for another 10 min recording. Point

844 tracking collected distance and velocity traveled. Distance moved was calculated using the Ethovision XT 11

845 software from Noldus, normalizing to habituation time. Raw data are provided in the Supplemental Excel

846 spreadsheet.

847

848 **Neuromuscular Junction Staining**

849 Larvae were fixed in 4% PFA. Alpha-Bungarotoxin AlexaFluor 488 conjugate (Invitrogen B13422) was used at

850 1:500, znp1 (anti-SYT2, Abcam ab154035) monoclonal antibody was used at 1:200, with secondary antibody

851 594 anti-mouse (Jackson #715-585-150) incubated at 1:500.

852

853 **Larval Head Measurements**

854 Larvae were deeply anesthetized in tricaine and immersed in methylcellulose for brightfield imaging on Leica

855 microscope. Larvae were oriented for dorsal measurements of dorsal head length, hindbrain head length, inter-

856 eye width and forebrain head length, and oriented for lateral measurements of head height, lateral head length,

857 eye width, eye height and lateral length. Schematic of measurements can be found in McCammon *et al.* 2017

858 (McCammon et al., 2017). Raw data and conversion measurements are provided in the Supplemental Excel

859 spreadsheet.

860

861 **Quantification and statistical analysis**

862 With exception to proteomic analysis in Figures 5C, 5D, 7E, 7H, all statistical analysis was performed in Prism.

863 Statistical test is denoted in the figure legend corresponding to the appropriate figure. Error bars represent

864 standard error of the mean. Asterisks are defined in each relevant figure legend. On the lipidomic analysis of

865 individual species, to correct p-values we had utilized Sidak's multiple comparisons post hoc test rather than

866 FDR. Note, we tried FDR for multiple hypothesis correction, and that method produced similar results. GO

867 SLIM analysis was performed with PANTHER Classification System (www.pantherdb.org) that combines

868 genomes, gene function classifications, pathways and statistical analysis tools to enable biologists to analyze

869 large-scale genome-wide experimental data (Mi et al., 2019). For the Proteomics analysis, the peptide

870 intensities of biological samples were analyzed with MSstats, an R package for statistical analysis, using the

871 options FDR=0.05 or 0.01, 'removeProtein_with1Feature=TRUE' and 'fewMeasurements="remove"'. The

872 labeled genes indicate lowest p-values. For post hoc colocalization analysis of iPSC differentiated neurons

873 (Table 2), individual cell somas were outlined by freehand in FIJI, followed by Coloc 2 colocalization analysis

874 between Synaptotagmin-1 (Channel 1) and PSD-95 (Channel 2). Neurons were isolated between 3 images per

875 genotype of representative images from Supplemental Fig. 1. Similar statistics are indicated between control

876 16pdel neurons.

Main Figure Titles and Legends

Figure 1. Augmented local field potential activity in 16pdel syndrome differentiated neuronal culture.

a) Local Field Potential (LFP) summary analyzed by log2 fold change between control and 16pdel patient

differentiated neurons. MEA activity was recorded over 30 min starting in media, followed by physiological and

high potassium chloride (KCl) solution. Data was summarized and pooled from 3 experiments. Control n = 9

(media), n = 17 (Physiological Solution), n = 13 (High KCl Solution). 16pdel n = 35 (media), n = 76

27

886 (Physiological Solution), n = 35 (High KCl Solution). Violin plot group analysis: Control - 16pdel 2-way ANOVA.

887 *p ≤ 0.05. Technical experimental replicates n = 3.

888 **b)** Increased sex specific activity in female 16pdel probands drives overall increased LFPs, compared to

889 unaffected controls. Media unaffected neurons (Control) male (♂) n = 3, Control female (♀) n = 6,16pdel

890 neurons (Proband) ♂ n = 21, Proband ♀ n = 14, Physiological Solution Control ♂ n = 7, Control ♀ n = 10,

891 Proband ♂ n = 38, Proband ♀ n = 38, High KCl Solution Control ♂ n = 6, Control ♀ n = 7, Proband ♂ n = 18,

892 Proband ♀ n = 17. Violin plot analysis: male vs female T-Test. ****p ≤ 0.0001.

893 **c)** Increased sex specific female electrogenic burst frequency analyzed by log2 fold change between 16pdel

894 male and female Media ♂ n = 21, ♀ n = 14, Physiological Solution ♂ n = 38, ♀ n = 38, High KCl Solution ♂ =

895 18, ♀ n = 17. Violin plot analysis: male vs female T-Test. *p ≤ 0.05. Technical experimental replicates n = 3.

896

897 **Figure 2. Significant lipid changes between control and 16pdel differentiated neurons.**

898 **a)** Total log2 fold change from normalized peak area of lipid class analysis from untargeted lipidomics. Bolded

899 and colored indicate statistically significant changes by T-Test, p ≤ 0.05 - 0.0001.

900 AcCa acyl carnitine, AEA N-arachidonoylethanolamine, Cer ceramide, ChE cholesterol ester, Co coenzyme,

901 DG diacylglycerol, Hex1Cer hexosylceramide, LPC lysophosphatiylcholine, LPE lysophosphatiylethanolamine,

902 LPG lysophosphatiylglycerol, MG monoacylglycerol, PA phosphatidic acid, PC phosphatidylcholine, PE

903 phosphatidylethanolamine, PG phosphatidylglycerol, PI phosphatidylinositol, PS phosphatidylserine, SM

904 sphingomyelin, SPH sphingosine,TG triacylglycerol.

905 **b)** Total lipid composition analysis from untargeted lipidomics between control and 16pdel neuron. Chain

906 Length: Small 1-5, Medium 6-12, Long 13-21, Very Long 22+, and Unresolved.

907 **c – f)** Selected analysis of lipid species from untargeted lipidomics classes. Lipid Class specified for each

908 histogram (c - phosphatidylethanolamine, d - ceramide, e - monoacylglycerol, f – triacylglycerol) normalized

909 peak area between control (grey) and 16pdel (orange). Statistical analysis by 2-Way ANOVA, *p ≤ 0.05 **p ≤

910 0.01,***p ≤ 0.001, ****p ≤ 0.0001. Control n = 10, 16pdel n= 69, error bars represent SEM. TG and PE long and

911 very long chain species not shown as no significant differences were found by ANOVA. Technical experimental

912 replicates n = 3.

913

914 **Figure 3. FAM57B interacts with CerS but does not have CerS activity.**

915 **a)** CerS2 activity assayed using C24:1-CoA in *CerS2 KO* HEK293T cells. Statistical analysis by T-test *p ≤

916 0.05, **p ≤ 0.01, error bars SEM. Technical experimental replicates n = 3.

917 **b)** (Upper) Western blot analysis of total human FAM57B-Flag and CerS2-HA after transfection in HEK293T

918 cells. Proteins were prepared from HEK293T cells overexpressing the indicated constructs. Anti-HA and anti-

919 Flag are indicated. (Lower) CerS2 activity assayed using C24:1-CoA in HEK293T cells. GAPDH was used as a

920 loading control. Statistical analysis by T-test *p ≤ 0.05, **p ≤ 0.01, error bars SEM. Technical experimental

921 replicates n = 3.

28

922 **c)** (Upper) Western blot analysis of total human FAM57B-Flag, CerS5-HA and CerS6-HA after transfection in

923 HEK293T cells. Proteins were prepared from cells overexpressing the indicated constructs. Anti-HA and anti-

924 Flag are indicated. (Lower) CerS5 and CerS6 activity was assayed using C16:0-CoA in HEK293T cells. Anti-

925 HA and anti-Flag are indicated. GAPDH was used as a loading control. Technical experimental replicates n =

926 4.

927 **d)** Total cell lysates were prepared from the co-transfected cells with FAM57B-Flag and CerS2, 5 or 6-HA

928 constructs and solubilized with 1% NP-40. Total lysates (input) or proteins immuno-precipitated with anti-Flag

929 M2 agarose (IP) were subjected to immunoblotting with anti-HA or anti-Flag antibodies. GAPDH was used as a

930 loading control. Technical experimental replicates n = 3.

931

932 **Figure 4. Significant lipid changes in sphingolipids and glycerolipids between WT and *FAM57B mutant***

933 **human differentiated SH-SY5Y neuronal cells.**

934 **a - c)** Total log2 fold change from normalized peak area of lipid class analysis from untargeted lipidomics. **a)**

935 *FAM57B KO* – WT, **b)** *FAM57B HET* – WT, **c)** *FAM57B KO – FAM57B HET*. Bolded and colored indicate

936 statistically significant changes by T-Test, p ≤ 0.05 - 0.0001. AcCa acyl carnitine, Cer ceramide, ChE

937 cholesterol ester, CL cardiolipin, Co coenzyme, DG diacylglycerol, HexCer Hexosylceramide, LPC

938 lysophosphatiylcholine, LPE lysophosphatiylethanolamine, MG monoacylglycerol, PC phosphatidylcholine, PE

939 phosphatidylethanolamine, PG phosphatidylglycerol, PI phosphatidylinositol, PS phosphatidylserine, SM

940 sphingomyelin, TG triacylglycerol. Technical experimental replicates n = 3.

941 **d – g)** Selected analysis of lipid species from untargeted lipidomics classes. Lipid Class specified for each

942 histogram, normalized peak area between WT (black) *FAM57B HET* (orange) and *FAM57B KO* (blue).

943 Statistical analysis by 2-Way ANOVA, *p ≤ 0.05 **p ≤ 0.01, ***p ≤ 0.001, ****p ≤ 0.0001. Color of asterisks

944 indicate comparison between WT – HET (orange), WT – KO (blue), HET – KO (black). WT n = 3, *FAM57B*

945 *HET* n= 3, *FAM57B KO* n = 3, error bars represent SEM. Experiment repeated twice, analysis was similar

946 between two separate runs.

947

948 **Figure 5. *FAM57B* knockout human neurons indicate altered synaptic composition.**

949 **a-b)** Isolated synaptosome protein abundance changes between **a)** *FAM57B KO* relative to WT and **b)**

950 *FAM57B HET* relative to WT (Log2 Fold). Labeled and colored indicating increased (purple) or decreased

951 (green) abundance. Only the top 20 proteins of statical significance were labeled in **c** and analyzed in **e-g**. WT

952 n = 8, HET n = 10, KO n = 7. Technical experimental replicates n = 3.

953 **c-e)** Gene ontology analysis of statistically significant synaptosome isolated proteins (e) in *FAM57B KO*

954 relative to WT. **e)** gene ontology pie graphs of top 20 decreased protein groups of cellular components,

955 molecular function, protein classes, biological processes and pathways. **f)** gene ontology figure legend.

956 **g)** Analysis of synaptic markers from isolated synaptosomes between all 3 genotypes. Bolded are significantly

957 decreased protein abundance of synaptic structural and maturation proteins, and vesicle regulation machinery.

958 INA – WT - HET & WT - KO, RAB11B – HET - KO, STXBP1 – WT - HET & WT - KO, YWHAZ – WT - HET &

959 WT - KO. 2-Way ANOVA, p ≤ 0.05 – 0.0001.

960 **f)** Isolated synaptosome lipid abundance between *FAM57B KO* relative to WT. Bolded text and color (purple

961 increased and green decreased) indicates statistically significant changes by T-Test, p ≤ 0.05 - 0.01. n = 6 per

962 genotype, technical experimental replicates n = 2. No statistically significant differences observed when

963 comparing FAM57B HET to WT, nor *FAM57B KO* to *FAM57B HET*.

964

965 **Figure 6. Significant lipid changes in ceramides and glycerols between AB and *fam57b mut* brain**

966 **tissue.**

967 **a**) Total log2 fold change from normalized peak area of lipid class analysis from untargeted lipidomics. Bolded

968 and colored indicate statistically significant changes by T-Test, p ≤ 0.05 - 0.0001. AcCa acyl carnitine, Cer

969 ceramide, ChE cholesterol ester, CL cardiolipin, Co coenzyme, DG diacylglycerol, HexCer Hexosylceramide,

970 LPC lysophosphatiylcholine, LPE lysophosphatiylethanolamine, MG monoacylglycerol, PC

971 phosphatidylcholine, PE phosphatidylethanolamine, PG phosphatidylglycerol, PI phosphatidylinositol, PS

972 phosphatidylserine, SM sphingomyelin, TG triacylglycerol. Technical experimental replicates n = 3.

973 **b – g)** Selected analysis of lipid species from untargeted lipidomics classes. Lipid Class specified for each

974 histogram, normalized peak area between AB (grey) and *fam57b mut* (green). Statistical analysis by 2-Way

975 ANOVA, *p ≤ 0.05 **p ≤ 0.01,***p ≤ 0.001, ****p ≤ 0.0001. AB n = 3, *fam57b mut* n= 3, error bars represent

976 SEM. Experiment repeated twice, analysis was similar between two separate runs. Individual MG species

977 between *fam57b het* to AB n.s. Not shown for space: 2-Way ANOVA analysis of TG. Increase in TG

978 (16:0_16:0_16:1) in *fam57b het* compared to AB (p ≤ 0.01).

979

980 **Figure 7. Loss of *fam57b* results in altered plasma membrane architecture early in development and**

981 **decreased localization of Synaptotagmin family at the synapse later in development.**

982 **a)** Schematic of Cholera toxin-B-488 (CT-B) injection into hindbrain ventricle of embryo and flat-mounted

983 midbrain region for imaging at 24 hpf.

984 **b)** Representative embryo midbrain imaging and quantification of CT-B labeling of AB compared to *fam57b*

985 *mut*. Punctate CT-B labeling (arrows), actin marker phalloidin indicates labelling of CT-B at the plasma

986 membrane, merged with DAPI. Quantification of puncta between WT (grey) and *fam57b mut* (green) CT-B (p ≤

987 0.05) T-Test. Scale bar = 5 µm. AB n = 16, *fam57b mut* n = 18. Error bars SEM, statistical analysis by T-test *p

988 ≤ 0.05. Technical experimental replicates n = 4.

989 **c)** Representative embryo midbrain imaging and quantification of duramycin-488 labeling of AB compared to

990 *fam57b mut*. Punctate duramycin labeling (arrows), actin marker phalloidin indicates labelling of duramycin at

991 the plasma membrane, merged with DAPI. Quantification of puncta between WT (grey) and *fam57b mut*

992 (green) Duramycin PE staining (p ≤ 0.05) T-Test. Scale bar = 5 µm. AB n = 8, *fam57b mut* n = 8. Error bars

993 SEM, statistical analysis by T-test *p ≤ 0.05. Technical experimental replicates n = 3.

994 **d)** Schematic of membrane protein labeling biotinylation assay and processing for MS/MS in 7 dpf larvae

995 brains.

996 **e)** Larvae brain total plasma membrane protein abundance changes between *fam57b mut* relative to AB (Log2

997 Fold). Statistically significant p ≤ 0.05 - 0.0001 proteins labelled, indicating increased (purple) or decreased

998 (green) abundance. Lowest abundance membrane protein Synaptotagmin-1a (red box). n = 3 per genotype.

999 **f)** Representative slice of 7 dpf whole larva brain mount with Sytaptotagmin-1a (green), GAD65/67 (red) and

1000 Beta-actin (magenta). Z-stack composite image merged with DAPI. Forebrain and midbrain areas of diffused

1001 Syt-1 localization (white arrows). Anatomical differences noted throughout brain, including (1) optic tectum and

1002 (2) corpus cerebelli (red arrows). Scale bar = 10 μm. Technical experimental replicates n = 2.

1003 **g)** Representative 7 dpf whole brain western blot indicate no significant change in total Syt-1a protein levels

1004 between *fam57b mut* relative to AB. Zebrafish larvae brains pooled (20 per genotype). Syt-1a protein

1005 abundance normalized to Beta-Actin loading control, repeated twice.

1006 **h)** Larvae brain total isolated synaptosome protein abundance changes between *fam57b mut* relative to AB

1007 (Log2 Fold). Statistically significant p ≤ 0.05 - 0.0001 proteins labelled, indicating increased (purple) or

1008 decreased (green) abundance. Low abundance Synaptotagmin-2a like protein (red box). n = 7 per genotype.

1009 Technical experimental replicates n = 2.

1010 **i-j)** Gene ontology analysis of statistically significant larvae synaptosome isolated proteins (h) in *fam57b mut*

1011 relative to AB. i) Gene ontology pie graphs of increased and decreased protein groups of cellular components,

1012 molecular function, protein classes, biological processes and pathways. j) Gene ontology figure legend.

1013 **k)** Analysis of Synaptotagmin family members from larvae isolated synaptosomes. Significantly decreased

1014 protein abundance of Syt1a and Syt2a by 2-Way ANOVA, **p ≤ 0.01, ****p ≤ 0.0001.

1015 **l)** Analysis of Synaptotagmin family members from differentiated SH-SY5Y isolated synaptosomes between all

1016 3 genotypes. Significantly decreased protein abundance of elongated ESYT1 by 2-Way ANOVA, *p ≤ 0.05, **p

1017 ≤ 0.01. Error bars SEM.

1018 **m)** Analysis of synaptic markers from larvae isolated synaptosomes. Significantly decreased protein

1019 abundance (bolded) of vesicle regulation machinery and glutamate receptor activity by 2-Way ANOVA, **p ≤

1020 0.01, ****p ≤ 0.0001.

1021

1022 **Figure 8. Decreased spontaneous brain activity and diminished behavioral response after stimuli**

1023 **presentation in *fam57b* mutants.**

1024 **a-b)** Local field potential (LFP) recordings in unanesthetized live larvae at 7dpf. Brain localized LFP recordings

1025 were pooled for each larva. **a)** Decreased average number, mean rate and inter-LFP interval (ILI) coefficient of

1026 variation of LFP in *fam57b mut* compared to AB (orange). No electrographic burst activity was identified in

1027 *fam57b mut* at standard 5 LFPs/100 ms. Decreased electrographic burst parameters, including duration,

1028 number of LFPs per burst, frequency and percentage at 3 LFPs/200ms (blue). **b)** Decreased average

1029 electrographic burst network activity and frequency, defined as a minimum or 3 electrographic bursts between

1030 2 electrodes simultaneously, in *fam57b mut* compared to AB (grey). AB n = 21, *fam57b mut* n = 24 over 6

1031 experiments. Statistical significance by unpaired T-test, *p ≤0.05, **p ≤ 0.01,*** p ≤ 0.001,**** p ≤ 0.0001.

1032 Technical experimental replicates n = 7.

1033 **c)** Representative LFP waveform in brain region, indicating smaller relative waveform in *fam57b mut* compared

1034 to AB.

1035 **d)** Representative LFP raster plot over experimental time frame, indicating less overall activity in *fam57b mut*

1036 compared to AB.

1037 **e)** Representative image of 7 dpf immersed in cooled agarose in contact with electrodes on 12-well CytoView

1038 MEA plate.

1039 **f)** Startle response behavioral assay. Light source was removed for 5 secs at 10 min intervals. Mean distance

1040 reported from tracked movement during 70 min assay. Decreased light startle response identified in *fam57b*

1041 *mut* compared to AB. Statistical analysis of each startle response by T-test **p ≤ 0.01, *** p ≤ 0.001, **** p ≤

1042 0.0001. Error bars SEM. No overall significant change in movement outside of the startle identified. AB n =

1043 125, *fam57b mut* n = 33 over 5 experiments.

1044 **g)** Seizure response behavioral assay. Normalized (baseline recording subtracted) mean distance from tracked

1045 movement after absence or presence of pentylenetetrazol (PTZ) 0.5 mM and 5 mM. Significantly increased

1046 seizure-induced movement observed at 5mM in AB, while increased movement observed at 0.5 and 5 mM

1047 PTZ in *fam57b mut*. Diminished overall seizure-induced movement at 5 mM in *fam57b mut* compared to AB.

1048 Relative fold change compared to absence of PTZ indicated below histogram. Statistical analysis of each

1049 condition by T-test *p≤ 0.05, *** p ≤ 0.001, **** p ≤ 0.0001. Error bars SEM. AB n = 166 (0 mM), 92 (0.5 mM),

1050 150 (5 mM), *fam57b mut* n = 91 (0 mM), 70 (0.5 mM), 56 (5mM) over 6 experiments.

1051 **h)** Model proposing role of Fam57b activity in the brain. Loss of function in *fam57b* mutants indicate significant

1052 changes in plasma membrane lipid groups alter architecture of plasma membrane early the developing brain.

1053 Architectural changes indicated by increased lipid raft abundance and aggregation. Altered plasma membrane

1054 homeostasis results in mis-localization of synaptic proteins, including synaptotagmins, after maturation.

1055 Decreased spontaneous brain and network activity suggests diminished synaptic function and developed

1056 circuits. As evidence has suggested spontaneous network activity shapes synaptic development, this cycles

1057 back to declined neuronal maturation and circuity. Molecular changes to synaptic function and decreased

1058 spontaneous brain activity translate to altered behavioral response after stimuli presentation.

Highlights

- Augmented LFP activity and sex-specific differences in 16pdel neurons.
- 16pdel neuronal lipidome indicated altered ceramide related species.
- FAM57B is a ceramide synthase modulator essential for lipid regulation in the brain.
- FAM57B functions in synaptogenesis, synapse architecture and composition.
